## Abstract

An annotated check-list of the marine benthic flora of the Spanish Basque coast, based on literature records and original data, is presented. According to the present taxonomy, the known list of algae totals 372 taxa (354 species and 18 infraspecific taxa), distributed as follows: 23 Cyanophyta, 221 Rhodophyta, 74 Heterokontophyta and 54 Chlorophyta. In addition, 16 taxa are considered as *taxa inquirenda* and 8 as *taxa excludenda*. For each taxon the vertical distribution, abundance estimation, and two first published records are given. Remarks on the most noteworthy features of the flora of the study area are included. The floristic character of Spanish Basque coast flora was compared with nearby regions applying Cheney's ratio [(Rhodophyta+Chlorophyta)/Phaeophyta, or (R+C)/P]. The resulting high value (4,09) indicates its warm-water character, which was already noted at the end of the xix century. From a physionomical point of view, Basque benthic vegetation resembles more closely that of southern regions (S Portugal, Morocco). The warming process of waters off the Basque coast during summer up to 22 °C is responsible for the absence or very rare occurrence of cold temperate species like large fucoids and kelps, which are common in Galicia and Brittany, and explains the abundance of numerous warm-temperate species as ceramiaceous algae.

**Key words:** benthic marine algae, biogeography, Cantabrian Sea, Chlorophyceae, Cyanophyceae, nomenclature, Phaeophyceae, Rhodophyceae, seaweeds, taxonomy.

## Introduction

Information concerning the algal flora of the Spanish Basque coast has been sparse and late-coming compared to information on other regions of the European

## Resumen

Se presenta un catálogo de la flora bentónica marina de la costa vasco-española basado en citas bibliográficas y algunos datos originales. De acuerdo con la taxonomía actual, la lista de algas conocidas asciende a 372 táxones (354 especies y 18 táxones infraespecíficos), que se distribuyen como sigue: 23 Cyanophyta, 221 Rhodophyta, 74 Heterokontophyta y 54 Chlorophyta. Además, 16 táxones se consideran como *taxa inquirenda* y 8 como *taxa excludenda*. Para cada taxón se ofrece información sobre su distribución vertical, una estimación de su abundancia y las dos primeras citas publicadas. Se incluyen comentarios sobre las características más destacables de la flora del área de estudio. Se compara el carácter florístico de la flora de la costa vasco-española con respecto a las regiones próximas aplicando el índice de Cheney [(Rhodophyta+Chlorophyta)/Phaeophyta, o (R+C)/P]. El elevado valor resultante (4,09) indica su carácter meridional, lo que ha sido señalado desde finales del siglo xix. Desde un punto de vista fisionómico la vegetación bentónica vasca se asemeja más a la de regiones meridionales (sur de Portugal, Marruecos). El calentamiento de las aguas de la costa vasca hasta 22 °C durante el verano es responsable de la falta o rareza de especies templado-frías como las fúcaceas y laminariales, comunes en Galicia y Bretaña, y explica la abundancia de numerosas especies templado-cálidas como las cerámicas.

**Palabras clave:** algas bentónicas marinas, biogeografía, cianofíticas, clorofíticas, feofíticas, macroalgas, mar Cantábrico, nomenclatura, rodofíticas, taxonomía.

Atlantic coast, such as England, Brittany, Galicia, Portugal and the nearby French Basque coast. The first list of marine macroalgae including Spanish Basque coast records was compiled by Colmeiro (1867) who reported 12 new records of Rhodophyta, 8 Heterokontophy-

ta and 4 Chlorophyta. Several works, mainly of Fisher-Piette (1935, 1955, 1963), increased the number of known species to 46 by the year 1965. The following noteworthy contribution was made by Hoek & Donze (1966), who reported 68 new records, including Cyanophyta. This work was the main reference source during the 1970's, a decade with few algological contributions. However, the knowledge of Basque seaweeds increased particularly during the 1980's (Angulo, 1980; Ibáñez & al., 1980; Gorostiaga, 1981; Gorostiaga & Límia, 1985; Gorostiaga & al., 1987, 1988; Casares, 1988, 1989; Casares & Seoane-Camba, 1988, 1989), when the number of known algae reached 270 taxa. Recent contributions have finally leveled the knowledge of the Spanish Basque coast algal flora with nearby areas (Gorostiaga & Santolaria, 1992; Bárbara & al., 1995; Gorostiaga, 1995; Díez & al., 1996; Secilla & al., 1997, 2000; Gorostiaga & al., 1998; Santolaria & al., 1998).

The aim of the present work is to compile for the first time the marine algal flora (Cyanophyta, Rhodophyta, Heterokontophyta and Chlorophyta) of the Spanish Basque coast. For this purpose a critical review of all published records has been carried out and we have supplemented this information with 37 new records of our collections. This check-list contributes to increasing the understanding of the biogeographical characteristics of this Atlantic area and the knowledge about its biodiversity.

## Material and Methods

The Spanish Basque coast is located in the northern part of the Iberian Peninsula, on the south-eastern corner of the Bay of Biscay (Fig. 1). It is mostly rocky with an exposed to very exposed shore and very few estuaries, all of them small. Following the coastline and including the estuaries, it extends over 300 km from Cape Higer ( $43^{\circ}23'46''N$ ;  $1^{\circ}47'24''W$ ) in the East to Kobaron Point ( $43^{\circ}21'01''N$ ;  $3^{\circ}09'58''W$ ) in the West. In political terms it comprises the Spanish provinces of Gipuzkoa and Bizkaia. The sea surface temperature ranges from  $11^{\circ}C$  to  $22^{\circ}C$  in February and August, respectively (Ibáñez, 1990; Borja & al., 2000). Biogeographically, it belongs to the warm temperate NE Atlantic sub-region (Hoek & Breeman, 1990).

The list of marine benthic algae (Cyanophyta, Rhodophyta, Heterokontophyta and Chlorophyta) was compiled after a careful review of all published records and supplemented by our own collections. Unpublished works such as M. Phil. Thesis, Ph.D. Doctoral Thesis and Technical Reports have not been considered. The data presented here date from Montagne (1842) to Díez & al. (2003). First and second records are given for each taxon.

Taxa are named with their nomenclatural authorities, and the names have been abbreviated following Brummitt & Powell (1992). In the Cyanophyta and Chlorophyta orders and families are arranged according to Silva & al. (1996), with some remarks by Komárek & Anagnostidis (1986) and Anagnostidis & Komárek (1988), for the first case. In Rhodophyta, we follow Garbary & Gabrielson (1990), with the addition of the Ahnfeltiales (Maggs & Pueschel 1989), the Gracilariales (Fredericq & Hommersand 1989) and the Plocamiales (Saunders & Kraft 1994), while the order Ceramiales is arranged according to Maggs & Hommersand (1993). The systematic treatment of Phaeophyceae follows Wynne & Kraft (1981). All genera and species are arranged alphabetically.

The present taxonomic status and nomenclatural changes of the taxa concerned have been considered. The check-list includes the synonyms under which a specific or infraspecific taxon has been recorded. Records that need to be confirmed are included in a separate list as *taxa inquirenda*. Likewise, a list of *taxa excludenda* is also given with pertinent comments and references. Specimens of most of the species included in this check-list are deposited in the herbaria of the Basque Country University (BIO), the University of Barcelona (BCF) and the University of Santiago de Compostela (SANT). Information about the abundance estimation and vertical distribution of each species is given together with an indication of the provinces (Gipuzkoa and Bizkaia) from which they have been reported.

The floristic character of Spanish Basque coast flora in relation to cold-water and warm-water poles was compared with that of southern England (Hardy & Guiry, 2003), Brittany (Feldmann, 1954; Feldmann & Magne, 1964; Coppejans, 1995), Galicia (Miranda, 1934; Donze, 1968; Pérez-Cirera, 1975a, 1975b; Niell, 1978; López Rodríguez & Pérez-Cirera, 1990, 1995, 1996; López Rodríguez & al., 1991, 2003; Gallardo & Margalef, 1992; Granja & al., 1992, 1993; Guillermes & Cremades, 1993, 1997; Guillermes & al., 1994; Bárbara & Cremades, 1996; Otero-Schmitt & Pérez-Cirera, 1996, 1998, 2002; Cremades & al., 1997b, 2002; Veiga & al., 1997, 1998a, 1998b; Bárbara & al., 2002, 2003; Calvo & Bárbara, 2002, 2003, in press; Peña & Bárbara, 2002, 2003a, 2003b), the Atlantic coast of the southern Iberian Peninsula (Ardré, 1970, 1971; Flores Moya & al., 1995a, 1995b; Conde & al., 1996; Conde & Flores Moya, 2000; Báez & al., 2001), Morocco (Benhissoune & al., 2001, 2002a, 2002b, 2003), the Canary Islands (Haroun & al., 2002) and the Mediterranean coast of Andalusia (Flores Moya & al., 1995a, 1995b; Conde & al., 1996) using Cheney's ratio [(R+C)/P] (Cheney, 1977).

**Fig. 1.** Map showing the location of the Spanish Basque Country and the regions with which its flora is compared.

## Results and Discussion

The known list of benthic marine algae from the Spanish Basque coast now totals 372 taxa (354 species and 18 infraspecific taxa): 23 Cyanophyta, 221 Rhodophyta, 74 Heterokontophyta and 54 Chlorophyta (Table 1). In addition, 16 taxa are considered as *taxa inquirenda* and 8 as *taxa excludenda*.

This flora includes several warm-temperate species which reach their northern limit of distribution in this area. Most of these species are rare or very rare on the Basque coast such as *Bryopsis pennata*, *Pedobesia simplex*, *Hydroclathrus clathratus*, *Sargassum vulgare*, *Ceramium tenerrimum*, *Chrysymenia ventricosa*, *Haliptilon virgatum* and *Pleonomosporium caribaeum*. However, within this group there are frequently found species such as *Colpomenia sinuosa*, *Spatoglossum solieri*, *Dasya rigidula* and *Peyssonnelia squamaria* and seasonally abundant species such as *Centroceras clavulatum* and *Hypnea musciformis*.

Various cold-temperate macrophytes (mostly fucoids and kelps) which are common along the coasts of Galicia, England and Brittany are not abundant on the Spanish Basque coast. These include: *Ascophyllum nodosum*, *Fucus ceranoides*, *F. spiralis*, *F. vesiculosus*, *Halidrys siliquosa*, *Laminaria ochroleuca*, *Pelvetia canaliculata*, *Saccorhiza polyschides*, *Chondrus crispus* and *Mastocarpus stellatus*. Other macrophytes frequently found in the nearby Atlantic regions but absent on the Basque coast are: *Chorda filum*, *Desmarestia aculeata*, *Fucus serratus*, *Himanthalia elongata*, *Laminaria digitata*, *L. hyperborea*, *L. saccharina*, *Delesseria sanguinea*, *Dilsea carnosa*, *Dumontia contorta*, *Membranoptera alata*, *Palmaria palmata*, *Phycodrys rubens* and *Rhodomela confervoides*.

The presence of *Colpomenia sinuosa*, *Hydroclathrus clathratus*, *Sargassum vulgare*, *Spatoglossum solieri*, *Centroceras clavulatum* and *Halopithys incurva* establishes interesting floristic differences with respect to the Northwest coast of Iberian Peninsula, where these species are absent. Likewise, among the benthic marine flora from the Basque coast should be emphasize the presence of an endemism, *Fucus chalonii*. There are only two known populations of this dwarf species of *Fucus* located at Andagorria inlet (French Basque coast) and at Ogeia inlet (Spanish Basque coast).

The most common macrophytes in the subtidal zone are: *Mesophyllum lichenoides*, *Gelidium sesquipedale*, *Cystoseira baccata*, *Pterosiphonia complanata*, *Falkenbergia rufolanosa* (the tetrasporophytic phase of *Asparagopsis armata*), *Zanardinia typus*, *Corallina officinalis*, *Codium decorticatum*, *Plocamium cartilagineum* and *Dictyota dichotoma* (Gorostiaga &

al., 1998; Díez & al., 2003). In the intertidal zone the most frequent macrophytes forming belts are the chlorophytes *Blidingia minima*, *Codium adhaerens*, *Ulva clathrata*, *U. compressa*, *U. rigida*, the brown algae *Bifurcaria bifurcata*, *Cladostephus spongiosus*, *Ralfsia verrucosa* and *Stylocaulon scoparium* as well as the rhodophytes *Corallina elongata*, *Caulacanthus ustulatus*, *Ceramium ciliatum*, *Chondracanthus acicularis*, *Chondria coerulescens*, *Gelidium spinosum*, *G. pusillum*, *Halopithys incurva*, *Jania rubens*, *Lithophyllum incrustans*, *L. byssoides*, *Osmundea pinnatifida* and *Pterosiphonia complanata*.

According to the literature consulted, the Cheney's ratio for the Basque coast (4.09) is high compared with nearby regions (Table 2), indicating its warm-winter character and, after data compiled by Álvarez & al. (1988), significantly greater than for the Atlantic Iberian Peninsula considered as a whole (3.10). From a phisonomical viewpoint, Basque benthic vegetation more closely resembles that of southern regions, due to the absence or very rare occurrence of large fucoids and kelps (in the intertidal and subtidal zones, respectively) and the presence of *Gelidium corneum* and *Cystoseira baccata* stands in the subtidal zone.

The present composition of seaweed floras at a worldwide scale is explained on the basis of species' temperature responses (in some cases in combination with photoperiod responses), and taking into account paleoclimatological aspects and the displacement of coastlines in geological periods (Athanasiadis, 1990; Hoek & al., 1990). The flora of the north coast of Spain falls within the warm temperate NE Atlantic subregion according to the phytogeographical scheme proposed by Hoek & Breeman (1990). However, on this coast, of similar latitude throughout, there are significant floristic differences between the western and eastern coasts, with the Basque coast flora showing fewer cold-temperate species and more Mediterranean species than that of Galicia. This 'southern character' of Basque coast flora may be explained by the fact that the surface water of this part of the Bay of Biscay is warmed in summer up to 22°C (August isotherm) in contrast to Galicia which only reaches 19°C. In addition, some areas of the northwest coast of Spain are affected by episodic upwelling events during summer. The warming process of waters off the Basque coast is the result of the entrainment of water masses in the southern corner of the Bay of Biscay due to the abatement of the winds and sea current regimes during summer (Borja & al., 1996).

Bornet (1892: footnote to pp. 167-168), who was apparently unfamiliar with the flora of Galicia, thought that

the flora of Biarritz (French Basque coast) extended without much change along the coast of Spain, Portugal, and Morocco. Sauvageau (1897), after seeing specimens of cold-water Fucales collected by Durieu de Maisonneuve at Gijón (Asturias) in 1835, doubted about Bornet's conclusion and, to settle the matter, collected along the north coast of Spain as far west as A Coruña (Galicia). He concluded that the flora of the Basque coast was an interruption of the flora that was common to Brittany and Galicia. Similarly, Feldmann & Lami (1941) pointed out the southern character of the Basque coast, describing it as "une enclave très remarquable d'une végétation à nombreux élément subtropicaux au sein de la région boréale tempérée". On the basis of data gathered from

literature and supplemented by personal observations, Hoek & Donze (1966, 1967) concluded that "floristically and as regards temperature-range of the surface-water, the Côte Basque finds its logical place in between Morocco and NW. Spain." Likewise, the same authors pointed out that the physionomical resemblance between the algal flora of the Basque coast and that of Morocco explains the stress placed by phycologists on the southern character of the algal flora of the Basque coast. Subsequently, Álvarez Cobelas & al. (1989), studying floristic data of Iberian Peninsula, found a great similarity between Gipuzkoa and the South of Portugal. As other works before, the results from our check-list emphasizes the meridional character of this Atlantic coast.

**Table 1.** Check-list of the benthic marine algae of the Spanish Basque coast. **B** = Bizkaia; **G** = Gipuzkoa; **A** = Abundance (**VR** = Very rare, occasional specimens; **R** = Rare, dispersed specimens with a low frequency of appearance; **F** = Frequent, dispersed specimens with a high frequency of appearance; **C** = Common, specimens forming patches; **VC** = Very common, specimens forming belts); **BL** = Bathymetric level (**Sd** = Deep sublittoral, >15 m depth; **Ss** = Shallow sublittoral, 0-15 m depth; **Li** = Low littoral, zone between low spring tide level and lower limit of barnacles belt; **Lm** = Mid littoral, barnacles belt; **Lh** = High littoral, zone between upper barnacles belt and upper limit of winkles; **P** = Pools); **1<sup>st</sup> R** = first published record; **2<sup>nd</sup> R** = second published record.

**Table 2.** Cheney's ratio [(Rhodophyta+Chlorophyta)/Phaeophyta] for the Spanish Basque coast and nearby areas (only taxa at species level).

Area	Chlorophyta	Phaeophyta	Rhodophyta	Total	(R+C/P)
Basque coast	51	65	215	331	4.09
Galicia	90	125	297	512	3.09
Brittany	104	156	334	594	2.81
Southern England	78	140	275	493	2.52
Atlantic coast of the southern Iberian Peninsula	41	60	184	285	3.75
Mediterranean coast of Andalusia	76	81	268	425	4.25
Morocco	102	131	379	612	3.67
Canary Islands	117	125	385	627	4.02

## Notes

1. After several works (e.g., Feldmann & Feldmann, 1953) which concluded that *Dermocarpa* P. Crouan & H. Crouan and *Xenococcus* Thur. were indistinguishable, Komárek & Anagnostidis (1986) adopted *Xenococcus*, and subsequently the family *Xenococcaceae* Ercegović as the names that have priority, because they considered the type species *Dermocarpa violacea* P. Crouan & H. Crouan to be taxonomically doubtful. However, Silva & al. (1996) pointed out that presently Dermocarpaceae and *Dermocarpa* are the correct names because no formal proposals have been submitted to reject them.
2. This species was assigned by Anagnostidis & Komárek (1988) to genus *Leptolyngbya*. Hoffman & Compère (1990) pointed out that the name *Leptolyngbya* Anagnostidis & Komárek was initially superfluous since the genus to which it applied included *Spirocoleus lagerheimii* Möbius, the type of *Spirocoleus*. After that, Silva & al. (1996) assigned it to the genus *Spirocoleus*.
3. This species was assigned by Anagnostidis & Komárek (1988) to *Leptolyngbya*, which resulted superfluous (Hoffman & Compère, 1990), so we have decided to maintain the name used in Geitler's treatment.
4. The systematic position of this taxon is uncertain and probably does not belong to the Acrochaetiaceae. According to Pueschel (1989) it probably belongs to Gigartinales.
5. Guiry (1997) recommends a revision of the generic placement of this species.
6. According to Silva & al. (1996) although the identity of *Gelidium corneum* has been ascertained by the examination of the type specimen (Dixon, 1967), most authors in the 20<sup>th</sup> century have unjustifiably rejected the name as being ambiguous. Likewise, Silva & al. (1996) add that *G. corneum* should be applied to the species currently known in Europe as *G. sesquipedale*.
7. We follow Fredriksen & al. (1994) in considering that *Gelidium pulchellum* and *G. pusillum* represent distinct entities at the species level.
8. We follow Silva & al. (1996) in their proposal of *Gelidium spinosum* as a new combination with *Gelidium latifolium* as a synonym.
9. See Silva & al. (1996) for the rejection of the nomenclatural authority of *Gelidium latifolium*.
10. Hoek & Donze (1966) reported *Gelidium latifolium* and *G. attenuatum* as distinct entities.
11. We follow Santelices & Hommersand (1997) in their proposal of *Pterocladiella* as a new genus.
12. According to Cremades & al. (1997a), most reports of *Amphiroa rigida* and *Amphiroa beauvoisii* J.V. Lamour. from European Atlantic coast should be referred to *A. van-bosseae*.
13. This species has been reported under the misapplied epithet 'tortuosa', either as *Tenarea tortuosa* or as *Lithophyllum tortuosum*. According to Woelkerling (1988) the correct name for this alga is *Lithophyllum byssoides*.
14. There are no voucher specimens from Borja & al. (1982) and Fernández & al. (1982) citations. From the revision of the material cited by Díez & al. (1996) and deposited in BIO, we conclude that material identified as *Halarachnion ligulatum* are scarcely developed specimens of *Gralelopia filicina*. The sporophytic stage *Cruoria rosea* (P. Crouan & H. Crouan) P. Crouan & H. Crouan has not been reported.
15. Silva & al. (1996) pointed out that the epithet commemorates Teede (the collector) and 'teedii' is corrected to 'teedei' in accordance with Rec. 60C.1(a) and Art. 60.11.
16. This taxon includes the tetrasporophytic stage, *Petrocelis cruenta* J. Agardh for which the first record was given by Bárbara & al. (1995). Despite its late discovery, both stages are frequent in the Basque coast.
17. Angulo (1980), Ibáñez & al. (1980) and Gorostiaga & al. (1981) reported this meridional taxon from the Basque coast, but no voucher specimens could be found until now.
18. This taxon includes the tetrasporophytic stage *Haematocelis rubens* J. Agardh which corresponds to the first citation of this species in the Basque coast (Hoek & Donze, 1966). The gametophytic stage was firstly reported by Gorostiaga (1981). Both stages are frequent in the study area.
19. The sporophytic stage *Haematocelis fissurata* P. Crouan & H. Crouan has not been reported.
20. According to Haroun & al. (2002) *Gracilaria gracilis* is an illegitimate name for *G. confervoides* (L.) Grev. These authors also consider that it falls within the original concept of *G. verrucosa* (Huds.) Papenf., part of which belongs to *Gracilariaopsis longissima* (S.G. Gmel.) Steentoft & al., also an illegitimate name.
21. The record of *Gracilaria foliifera* (Forssk.) Børgesen by Casares & Seoane-Camba (1988) is included. The conspecificity of *Gracilaria multipartita* and *G. foliifera* was proposed by Børgesen (1932). However, Guiry & Freamhainn (1985) suggested that *G. multipartita* is a distinct species confined to the eastern North Atlantic coasts.
22. This species includes the sporophytic stage *Falkenbergia rufolanosa* (Harv.) F. Schmitz, which is the dominant stage in the Basque coast. The first records including the gametophytic stage were Angulo (1980) and Ibáñez & al. (1980).
23. The sporophytic stage *Hymenoclonium serpens* (P. Crouan & H. Crouan) Batters has not been recorded.
24. This species includes the sporophytic stage, *Trailliella intricata* Batters. The gametophytic stage is more abundant in the Basque coast. The first citations of this species included both stages.
25. We follow Athanasiadis (1987) in considering *Aglaothamnion neglectum* as a synonym of *A. cordatum*; Silva & al. (1996) listed them as distinct species.
26. We follow Maggs & Hommersand (1993) in referring to this species as *Aglaothamnion brodiae* and *Callithamnion brodiae* based on Feldmann-Mazoyer's concept of *A. brodiei* ('brodiae').
27. We follow Dixon & Price (1981) in considering *Aglaothamnion scopulorum* and *Callithamnion polyspermum* to be synonym of *A. hookeri*. According to Maggs & Hommersand (1993) further critical biosystematic studies are needed.
28. We follow Furnari & al. (1998) in considering *Aglaothamnion byssoides* conspecific with *A. tenuissimum*.
29. A revision of the material reported as *Antithamnionella elegans* in Díez & al. (1999), kept at BIO, reveals that it corresponds to *A. elegans* var. *boergesenii*. We follow Athanasiadis (1996) in recognising *A. boergesenii* as a distinct species, segregated from *A. elegans* var. *breviramosa*, *A. elegans* var. *elegans* and *A. elegans* var. *sublittoralis*. These 4 taxa were previously recognised by Cormaci & Furnari (1988) as separate varieties of *A. elegans*.
30. *Callithamnion tetragonum* var. *brachiatum* is currently considered to be a growth form of *C. tetragonum* (Dixon & Price, 1981).
31. Following Maggs & Hommersand (1993) records of *C. tenuissimum* are included in *C. diaphanum*.
32. This species includes var. *corticatum* Mazoyer.
33. We follow P.C. Silva (1996) who proposed conserving *Ceramium rubrum* with a neotype in contrast to Maggs & Hommersand (1993) whom proposed the name *C. nodulosum* for this species.
34. As Abdelahad & D'Archino (1998) did for Mediterranean records, we refer *Ceramium rubrum* var. *barbatum* records from the Basque coast to *C. secundatum*.
35. According to Wynne (1989) *Acrosorium uncinatum* is conspecific with *A. venulosum* from the Mediterranean Sea. Like-

- wise, records of *Cryptopleura uncinata* [= *Nitophyllum uncinatum* J. Agardh] have been referred to *A. venulosum*. John & al. (2004) considered *A. uncinatum* and *Nitophyllum uncinatum* as synonyms of *A. ciliolatum*.
36. Records of *Acrosorium reptans* have been considered as a prostrate growth form of *Cryptopleura ramosa* following Wynne (1989).
  37. The transfer of *Myriogramme minuta* into *Drachiella minuta* (Maggs & Hommersand, 1993) appears to be unjustified according to Wynne (1994).
  38. *Dasya arbuscula* (Dillwyn) C. Agardh is based on *Conferva arbuscula* Dillwyn, a species that should be referred to the genus *Aglaothamnion* (Maggs & Hommersand, 1993). However, we refer to *D. hutchinsiae* all the records of *D. arbuscula* from the Basque coast, considering that they fall within Harvey's (1849: pl. 224) taxonomic concept of the species.
  39. The systematic position of this taxon is uncertain (Stegenga & al., 1997).
  40. Records of *Polysiphonia caespitosa* (Pocock) Hollenb. cited as *Falkenbergiella caespitosa* Pocock (Bárbara & al., 1995; Secilla & al., 2000) are included here because they are considered to be a misidentification of *Polysiphonia scopulorum*.
  41. We refer to this species the *Pterosiphonia spinifera* records since we think that authors most probably referred to *P. spinifera* var. *robusta* Ardré, nom. illeg. (= *P. ardeana*).
  42. Santolaria & al. (1998) cited both *Feldmannia paradoxa* and *F. globifera*, which are synonyms.
  43. According to Fletcher (1987) *Hecatonema terminale* is a taxonomic synonym of *H. maculans*; however, according to Wynne (1998), the former name has priority with the basionym *Ectocarpus terminalis* Kütz. As several authors have pointed out (Fletcher, 1987; Wynne, 1998) this entity may represent the microthalli of various taxa, including *Punctaria* (Clayton, 1974), *Myriotrichia* (Loiseaux, 1969) and *Asperococcus* (Pedersen, 1984).
  44. Records from Gipuzkoa correspond to drift material.
  45. Montagne (1842) reported one specimen of *Desmarestia pinnatinervia* from the San Sebastián harbour. This species was considered later as a synonym of *Desmarestia dudresnayi* by Sauvageau (1925). According to Guiry & Nic Dhonncha (2003) the taxonomical position of *D. pinnatinervia* is dubious. Recently, we have found 2 specimens of *D. dudresnayi* at 30 m depth on an old wrecked ship in the locality of Zierbena (Bizkaia).
  46. This species includes the sporophytic stage, *Aglaozonia melanoidea* Schousboe ex Bornet.
  47. The first record corresponds to the sporophytic stage *Aglaozonia parvula*. The gametophytic stage was firstly reported by Casares & Seoane (1989) as drift material, being the first attached specimens cited by Santolaria & al. (1998).
  48. At present, only a small population of this species occurs in the Spanish Basque coast (Txatxarramendi). In addition, the scarce specimens show a stunted morphology.
  49. This species was firstly observed by G. Hamel in Cap Higer (in Feldmann & Lami, 1941: 133).
  50. Chalon (1905) pointed out the presence of a small form of *Fucus limitaneus* at Andagorria inlet (French Basque coast) and Cape Higer. After that, Feldmann (1941) described it as a new species, *Fucus chalonii*. Two facts lead us to consider Chalon's *F. limitaneus* from Cape Higer as really *Fucus spiralis* var. *limitaneus*: 1) presently, *F. chalonii* does not occur at Cape Higer, and 2) the habitat of *F. chalonii* is very different. Therefore, we consider that record as the first of *F. spiralis* var. *limitaneus* for the Spanish Basque coast.
  51. In this variety, proposed as a new combination by Pérez-Ruzaña (Gómez-Garreta, 2001), we have included all records of *Fucus* with the epithet of 'limitaneus' or 'nanus' at the level of species, variety or form. However, on the Basque coast there is a variety of *F. spiralis* of a reduced size with a morphology and habitat which does not fall under the description given for *F. spiralis* var. *limitaneus*. Seoane-Camba (1975) described this reduced variety of *F. spiralis* as "Type C", one of the four morphological types that he recognized at Cape Higer. Its thallus is 6 cm long, has long cylindrical receptacles without a sterile edge, and lives in the upper eulittoral level of very exposed wave areas. Further investigations are needed to determine the taxonomic status of this variety.
  52. The taxonomy of this green algae group originally assigned to the Chaetophoraceae is in a changeable state. We follow Silva & al. (1996), who adopted an arbitrary compromise with references to alternative opinions.
  53. Contrary to Gayral (1965), Golden & Garbary (1984) consider *Ulvaria* as a subgenus of *Monostroma*. In the check-list of the Mediterranean Chlorophyceae, Gallardo & al. (1993) retain *Ulvaria* as a genus, considering *Monostroma oxyspermum* as a synonym of *U. oxysperma* (Kütz.) Bliding.
  54. Recent works (Tan & al., 1999; Hayden & al., 2003) have provided evidences that *Ulva* and *Enteromorpha* are not distinct evolutionary entities, with *Ulva* being the oldest name.
  55. Bae & Lee (2001) have recently proposed *Umbraulva* as a new genus to which *Ulva olivascens* was assigned.
  56. In contrast to Burrows (1991) who considers that *Chaetomorpha aerea* is conspecific with *C. linum*, we follow Blair (1983) in considering these species to be distinct.
  57. We follow Gallardo & al. (1993), who consider *Chaetomorpha mediterranea* a separate taxonomic identity from *Rhizoclonium tortuosum*, in contrast to Silva & al. (1996).
  58. This species includes *Cladophora pseudopellucida* (Hoek 1979).
  59. Hoek (1963) previously recorded this species floating on salt-marsh pools near Hondarribia (Gipuzkoa).
  60. We follow Silva & al. (1996) in considering *Rhizoclonium riparium* and *R. tortuosum* as distinct species. Gallardo & al. (1993) however, consider them as synonyms.
  61. See Gallardo & al. (1993) in relation to the proposal of this new name for *Bryopsis cupressoides* Kütz. *sensu* J. Feldmann and *B. cupressoides* J.V. Lamour. *sensu* Kütz.
  62. Records of the gametophytic stage, known as *Halicystis parvula* Schmitz ex Murray, are included. Gorostiaga & Díez (1996) firstly reported this stage from the Basque coast.
  63. *Pedobesia simplex* is a new name for *P. lamourouxii* Wynne & Leliaert (2001).

## Taxa Inquirenda

### Cyanophyceae

*Schizotrix calcicola* (C. Agardh) Gomont.—The presence of this taxon in the Basque coast, reported by Hoek & Donze (1966), needs to be confirmed since its habitat is not marine.

### Rhodophyceae

*Gymnogongrus patens* (Gooden. et Woodw.) J. Agardh.—This cold-water taxon has been reported by Angulo (1980), Ibáñez & al. (1980) and Gorostiaga (1981), but no voucher specimens could be found until now. After studying the material kept at BIO, we conclude that all the specimens identified as *G. patens* are *Ahnfeltiopsis devoniensis*, thus the

occurrence of the first in the Basque coast should be confirmed.

*Phyllophora herediae* (Clemente) J. Agardh.—This taxon has not been mentioned after Colmeiro (1867); its presence in the Basque coast needs to be confirmed.

*Phymatolithon calcareum* (Pall.) Adey & D.L. McKibbin.—Hoek & Donze (1966) reported *Lithothamnion polymorphum* (L.) Aresch. nom. illeg. [currently regarded as a synonym of *P. calcareum*] from Cape Higuer, growing on turf-forming algae sub-zone. This habitat does not correspond to the free-living *P. calcareum*, which occurs in the sublittoral zone up to 25 m depth.

*Polysiphonia foetidissima* Cocks ex Bornet.—This species was reported only by Gorostiaga & Díez (1996), but there are no voucher specimens to confirm its presence in the Basque coast.

*Polysiphonia lanosa* (L.) Tandy.—Angulo (1980) and Ibáñez & al. (1980) reported this species as *Vertebrata lanosa* (L.) T.A. Christensen from only one locality, and associated to *Ascophyllum nodosum*. Recent surveys in this locality have not confirmed the occurrence of *P. lanosa*.

*Rhodymenia coespitosella* L'Hardy-Halos.—Gorostiaga & al. (1987) and Gorostiaga & Díez (1996) reported this taxon from the Basque coast, but its occurrence needs to be confirmed. After studying the *R. coespitosella* specimens kept at BIO, we conclude that all specimens should be referred to *R. holmesii*.

#### Phaeophyceae

*Cystoseira barbata* (Stackh.) C. Agardh.—No further information was given for this Mediterranean taxon after Lázaro Ibiza (1893).

*Cystoseira foeniculacea* (L.) Grev.—Colmeiro (1867) cited this species as *C. abrotanifolia* (L.) C. Agardh; no further information was given for this taxon.

*Cystoseira platyclada* Sauv.—This taxon was reported by Casares (1989) and Casares & Seoane-Camba (1989). However, according to the morphology and habitat described by Casares (1987), we consider that it should be better referred to *C. usneoides*.

*Dictyota implexa* J.V. Lamour.—No further information was given for this meridional taxon after Colmeiro (1867). Probably, he referred to *D. dichotoma* var. *implexa* (Desf.) Gray, a taxonomic synonym of *D. dichotoma* var. *intricata*.

*Elachista scutulata* (Sm.) Duby.—The only record by Casares & Seoane-Camba (1989) corresponds to drift material.

*Isthmoplea sphaerophora* (Carmichael) Kjellm.—The

taxonomical position of *Isthmoplea sphaerophora* is unclear (Jaasund, 1960). Its occurrence in the Basque coast should be confirmed since there is only one report (Borja & al., 1982) and no voucher specimens could be found.

*Sargassum acinarium* (L.) Setch.—Lázaro Ibiza (1893) reported this meridional taxon as *Sargassum linifolium* C. Agardh. No further information was given.

#### Chlorophyceae

*Codium effusum* (Raf.) Delle Chiaje.—Fischer-Piette (1963) reported this taxon as *C. difforme* Kütz.; this species has a meridional distribution and no further information has been given for it, therefore its occurrence in the Basque coast should be confirmed.

*Urospora bangioides* (Harv.) Holmes et Batters.—This taxon has been only reported by Fernández & al. (1982). Its occurrence in the Basque coast should be confirmed since it mainly has a northerly distribution and there are no voucher specimens to confirm its presence in the Basque coast. On the other hand, the status of this taxon is in some way dubious and requires further investigation (Guiry & Dhonncha, 2003).

#### Taxa Excludenda

##### Rhodophyceae

*Aglaothamnion bipinnatum* (P. Crouan & H. Crouan) Feldm.-Maz.—After studying the specimens cited by Secilla & al. (2000), kept at BIO, we conclude that they belong in *A. tripinnatum*.

*Antithamnion tenuissimum* (Hauck) Schiffner.—Casares (1988, 1989) reported this taxon from Guipúzcoa. According to Athanasiadis (1996), extra-Mediterranean records of *A. tenuissimum* are *A. villosum*.

*Palmaria palmata* (L.) Kuntze.—Angulo (1980), Borja & al. (1982), Fernández & al. (1982) and Pérez-Celorio & al. (1995) reported *Rhodymenia palmata* (L.) Grev., a synonym of *P. palmata*. These records should be a misspelling for *R. palmetta* [currently regarded as *R. pseudopalmetta*], a frequent taxon in the area studied.

##### Phaeophyceae

*Himanthalia elongata* (L.) Gray.—All records (Angulo, 1980; Casares, 1989) of this northern taxon correspond to drift material.

*Laminaria digitata* (Huds.) J.V. Lamour.—Colmeiro (1867) and Ibáñez & al. (1980) reported this species from the Basque coast. Seoane-Camba (1966) concluded that all Iberian Peninsula records

of this northern taxon are misidentifications for, mainly, *L. ochroleuca*.

*Laminaria hyperborea* (Gunnerus) Foslie.—This northern taxon is absent in the Basque coast (Seoane-Camba, 1966). The record of Ibáñez & al. (1980) corresponds to drift material.

### Chlorophyceae

*Bryopsisella neglecta* (Berthold) Rietema.—After studying the specimens cited by Gorostiaga & Díez (1996) as *Bryopsisella halymeniae* (Berthold) Feldmann (kept in BIO), we conclude that they belong in *Derbesia tenuissima*.

*Ulva lactuca* L.—Several authors have reported this species from the Basque coast (e.g., Hoek & Donze, 1966; Angulo, 1980; or Ibáñez & al., 1980). According to Bliding (1968) this species has a more northern distribution (Artic region, Scandinavia and Great Britain). On the basis of its geographical distribution this species should be excluded from the Basque coast, as Hoeksema & Hoek (1983) excluded it from Roscoff (Brittany, France). According to Ibáñez & al. (1980), the records of *U. lactuca* from the Basque coast should be referred to *U. gigantea* (Kütz.) Bliding, but we consider that they are *U. pseudocurvata*.

### Acknowledgements

We are very grateful to P.C. Silva who criticised and greatly improved a previous version of the manuscript. We also thank Silvia Calvo from the Universidad de A Coruña (Dpto. de Biología Animal, Biología Vegetal y Ecología) for her assistance in the identification of the blue-green algae, as well as two anonymous reviewers by their valuable contributions that have greatly improve this work.
